(54) Title: ACCESSING NETWORK-BASED ELECTRONIC INFORMATION THROUGH SCRIPTED ONLINE INTERFACES USING SPOKEN NATURAL LANGUAGE INPUT

(57) Abstract: A system, method, and article of manufacture are provided for navigating an electronic data source that has a scripted online interface by means of spoken natural language. When a spoken natural language input request is received from a user, it is interpreted. A navigation query is constructed based on the interpretation of the speech input and a template extracted by scraping an online scripted interface to the data source. The resulting interpretation of the request is thereupon used to automatically construct an operational navigation query to retrieve the desired information from one or more electronic network data sources, which is then transmitted to a client device of the user.

**ACCESSING NETWORK-BASED ELECTRONIC INFORMATION THROUGH SCRIPTED
ONLINE INTERFACES USING SPOKEN NATURAL LANGUAGE INPUT**

BACKGROUND OF THE INVENTION

5 This is a Continuation In Part of co-pending U.S. Patent Application No.
09/225,198, filed January 5, 1999, Provisional U.S. Patent Application No.
60/124,718, filed March 17, 1999, Provisional U.S. Patent Application No.
60/124,720, filed March 17, 1999, and Provisional U.S. Patent Application No.
60/124,719, filed March 17, 1999, from which applications priority is claimed and
10 these application are incorporated herein by reference.

 The present invention relates generally to the navigation of electronic data by
means of spoken natural language requests, and to feedback mechanisms and methods
for resolving the errors and ambiguities that may be associated with such requests.

 As global electronic connectivity continues to grow, and the universe of
15 electronic data potentially available to users continues to expand, there is a growing
need for information navigation technology that allows relatively naïve users to
navigate and access desired data by means of natural language input. In many of the
most important markets -- including the home entertainment arena, as well as mobile
computing -- spoken natural language input is highly desirable, if not ideal. As just
20 one example, the proliferation of high-bandwidth communications infrastructure for
the home entertainment market (cable, satellite, broadband) enables delivery of
movies-on-demand and other interactive multimedia content to the consumer's home
television set. For users to take full advantage of this content stream ultimately
requires interactive navigation of content databases in a manner that is too complex
25 for user-friendly selection by means of a traditional remote-control clicker. Allowing
spoken natural language requests as the input modality for rapidly searching and
accessing desired content is an important objective for a successful consumer
entertainment product in a context offering a dizzying range of database content
choices. As further examples, this same need to drive navigation of (and transaction
30 with) relatively complex data warehouses using spoken natural language requests
applies equally to surfing the Internet/Web or other networks for general information,
multimedia content, or e-commerce transactions.

In general, the existing navigational systems for browsing electronic databases and data warehouses (search engines, menus, etc.), have been designed without navigation via spoken natural language as a specific goal. So today's world is full of existing electronic data navigation systems that do not assume browsing via natural spoken commands, but rather assume text and mouse-click inputs (or in the case of TV remote controls, even less). Simply recognizing voice commands within an extremely limited vocabulary and grammar -- the spoken equivalent of button/click input (e.g., speaking "channel 5" selects TV channel 5) -- is really not sufficient by itself to satisfy the objectives described above. In order to deliver a true "win" for users, the voice-driven front-end must accept spoken natural language input in a manner that is intuitive to users. For example, the front-end should not require learning a highly specialized command language or format. More fundamentally, the front-end must allow users to speak directly in terms of what the user ultimately wants -- e.g., "I'd like to see a Western film directed by Clint Eastwood" -- as opposed to speaking in terms of arbitrary navigation structures (e.g., hierarchical layers of menus, commands, etc.) that are essentially artifacts reflecting constraints of the pre-existing text/click navigation system. At the same time, the front-end must recognize and accommodate the reality that a stream of naïve spoken natural language input will, over time, typically present a variety of errors and/or ambiguities: e.g., garbled/unrecognized words (did the user say "Eastwood" or "Easter"?), and under-constrained requests ("Show me the Clint Eastwood movie"). An approach is needed for handling and resolving such errors and ambiguities in a rapid, user-friendly, non-frustrating manner.

What is needed is a methodology and apparatus for rapidly constructing a voice-driven front-end atop an existing, non-voice data navigation system, whereby users can interact by means of intuitive natural language input not strictly conforming to the step-by-step browsing architecture of the existing navigation system, and wherein any errors or ambiguities in user input are rapidly and conveniently resolved. The solution to this need should be compatible with the constraints of a multi-user, distributed environment such as the Internet/Web or a proprietary high-bandwidth content delivery network; a solution contemplating one-at-a-time user interactions at a single location is insufficient, for example.

SUMMARY OF THE INVENTION

The present invention addresses the above needs by providing a system, method, and article of manufacture for navigating network-based electronic multimedia data sources that contain multimedia content in response to spoken NL input requests. When a spoken natural language input request is received from a user, it is interpreted, such as by using a speech recognition engine to extract speech data from acoustic voice signals, and using a natural language parser to linguistically parse the speech data. The interpretation of the spoken natural language request can be performed on a computing device locally with the user or remotely from the user. A navigation query is constructed based on the interpretation of the speech input and a template extracted by scraping an online scripted interface to the data source. The resulting interpretation of the request is thereupon used to automatically construct an operational navigation query to retrieve the desired information from one or more electronic network data sources, which is then transmitted to a client device of the user.

Typically, errors or ambiguities emerge in the interpretation of the spoken NL request, such that the system cannot instantiate a complete, valid navigational template. This is to be expected occasionally, and one preferred aspect of the invention is the ability to handle such errors and ambiguities in relatively graceful and user-friendly manner. Instead of simply rejecting such input and defaulting to traditional input modes or simply asking the user to try again, a preferred embodiment of the present invention seeks to converge rapidly toward instantiation of a valid navigational template by soliciting additional clarification from the user as necessary, either before or after a navigation of the data source, via multimodal input, i.e., by means of menu selection or other input modalities including and in addition to spoken natural language. This clarifying, multi-modal dialogue takes advantage of whatever partial navigational information has been gleaned from the initial interpretation of the user's spoken NL request. This clarification process continues until the system converges toward an adequately instantiated navigational template, which is in turn used to navigate the network-based data and retrieve the user's desired information.

The retrieved information is transmitted across the network and presented to the user on a suitable client display device.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention, together with further advantages thereof, may best be understood by reference to the following description taken in conjunction with the accompanying drawings in which:

5 Figure 1a illustrates a system providing a spoken natural language interface for network-based information navigation, in accordance with an embodiment of the present invention with server-side processing of requests;

 Figure 1b illustrates another system providing a spoken natural language interface for network-based information navigation, in accordance with an
10 embodiment of the present invention with client-side processing of requests;

 Figure 2 illustrates a system providing a spoken natural language interface for network-based information navigation, in accordance with an embodiment of the present invention for a mobile computing scenario;

 Figure 3 illustrates the functional logic components of a request processing
15 module in accordance with an embodiment of the present invention;

 Figure 4 illustrates a process utilizing spoken natural language for navigating an electronic database in accordance with one embodiment of the present invention;

20 Figure 6 illustrates an embodiment of the present invention utilizing a community of distributed, collaborating electronic agents.

DETAILED DESCRIPTION OF THE INVENTION

1. System Architecture

a. Server-End Processing of Spoken Input

Figure 1a is an illustration of a data navigation system driven by spoken natural language input, in accordance with one embodiment of the present invention. As shown, a user's voice input data is captured by a voice input device 102, such as a microphone. Preferably voice input device 102 includes a button or the like that can be pressed or held-down to activate a listening mode, so that the system need not continually pay attention to, or be confused by, irrelevant background noise. In one preferred embodiment well-suited for the home entertainment setting, voice input device 102 is a portable remote control device with an integrated microphone, and the voice data is transmitted from device 102 preferably via infrared (or other wireless) link to communications box 104 (e.g., a set-top box or a similar communications device that is capable of retransmitting the raw voice data and/or processing the voice data) local to the user's environment and coupled to communications network 106. The voice data is then transmitted across network 106 to a remote server or servers 108. The voice data may preferably be transmitted in compressed digitized form, or alternatively --particularly where bandwidth constraints are significant-- in analog format (e.g., via frequency modulated transmission), in the latter case being digitized upon arrival at remote server 108.

At remote server 108, the voice data is processed by request processing logic 300 in order to understand the user's request and construct an appropriate query or request for navigation of remote data source 110, in accordance with the interpretation process exemplified in Figure 4 and Figure 5 and discussed in greater detail below. For purposes of executing this process, request processing logic 300 comprises functional modules including speech recognition engine 310, natural language (NL) parser 320, query construction logic 330, and query refinement logic 340, as shown in Figure 3. Data source 110 may comprise database(s), Internet/web site(s), or other electronic information repositories, and preferably resides on a central server or servers -- which may or may not be the same as server 108, depending on the storage

and bandwidth needs of the application and the resources available to the practitioner. Data source 110 may include multimedia content, such as movies or other digital video and audio content, other various forms of entertainment data, or other electronic information. The contents of data source 110 are navigated -- i.e., the contents are
5 accessed and searched, for retrieval of the particular information desired by the user -- using the processes of Figures 4 and 5 as described in greater detail below.

Once the desired information has been retrieved from data source 110, it is electronically transmitted via network 106 to the user for viewing on client display device 112. In a preferred embodiment well-suited for the home entertainment setting,
10 display device 112 is a television monitor or similar audiovisual entertainment device, typically in stationary position for comfortable viewing by users. In addition, in such preferred embodiment, display device 112 is coupled to or integrated with a communications box (which is preferably the same as communications box 104, but may also be a separate unit) for receiving and decoding/formatting the desired
15 electronic information that is received across communications network 106.

Network 106 is a two-way electronic communications network and may be embodied in electronic communication infrastructure including coaxial (cable television) lines, DSL, fiber-optic cable, traditional copper wire (twisted pair), or any other type of hardwired connection. Network 106 may also include a wireless
20 connection such as a satellite-based connection, cellular connection, or other type of wireless connection. Network 106 may be part of the Internet and may support TCP/IP communications, or may be embodied in a proprietary network, or in any other electronic communications network infrastructure, whether packet-switched or connection-oriented. A design consideration is that network 106 preferably provide
25 suitable bandwidth depending upon the nature of the content anticipated for the desired application.

b. Client-End Processing of Spoken Input

Figure 1b is an illustration of a data navigation system driven by spoken natural language input, in accordance with a second embodiment of the present
30 invention. Again, a user's voice input data is captured by a voice input device 102, such as a microphone. In the embodiment shown in Figure 1b, the voice data is

transmitted from device 202 to requests processing logic 300, hosted on a local speech processor, for processing and interpretation. In the preferred embodiment illustrated in Figure 1b, the local speech processor is conveniently integrated as part of communications box 104, although implementation in a physically separate (but
5 communicatively coupled) unit is also possible as will be readily apparent to those of skill in the art. The voice data is processed by the components of request processing logic 300 in order to understand the user's request and construct an appropriate query or request for navigation of remote data source 110, in accordance with the interpretation process exemplified in Figures 4 and 5 as discussed in greater detail
10 below.

The resulting navigational query is then transmitted electronically across network 106 to data source 110, which preferably resides on a central server or servers 108. As in Figure 1a, data source 110 may comprise database(s), Internet/web site(s), or other electronic information repositories, and preferably may include
15 multimedia content, such as movies or other digital video and audio content, other various forms of entertainment data, or other electronic information. The contents of data source 110 are then navigated -- i.e., the contents are accessed and searched, for retrieval of the particular information desired by the user -- preferably using the process of Figures 4 and 5 as described in greater detail below. Once the desired
20 information has been retrieved from data source 110, it is electronically transmitted via network 106 to the user for viewing on client display device 112.

In one embodiment in accordance with Figure 1b and well-suited for the home entertainment setting, voice input device 102 is a portable remote control device with an integrated microphone, and the voice data is transmitted from device 102
25 preferably via infrared (or other wireless) link to the local speech processor. The local speech processor is coupled to communications network 106, and also preferably to client display device 112 (especially for purposes of query refinement transmissions, as discussed below in connection with Figure 4, step 412), and preferably may be integrated within or coupled to communications box 104. In
30 addition, especially for purposes of a home entertainment application, display device 112 is preferably a television monitor or similar audiovisual entertainment device, typically in stationary position for comfortable viewing by users. In addition, in such

preferred embodiment, display device 112 is coupled to a communications box (which is preferably the same as communications box 104, but may also be a physically separate unit) for receiving and decoding/formatting the desired electronic information that is received across communications network 106.

5 Design considerations favoring server-side processing and interpretation of spoken input requests, as exemplified in Figure 1a, include minimizing the need to distribute costly computational hardware and software to all client users in order to perform speech and language processing. Design considerations favoring client-side processing, as exemplified in Figure 1b, include minimizing the quantity of data sent
10 upstream across the network from each client, as the speech recognition is performed before transmission across the network and only the query data and/or request needs to be sent, thus reducing the upstream bandwidth requirements.

c. Mobile Client Embodiment

A mobile computing embodiment of the present invention may be
15 implemented by practitioners as a variation on the embodiments of either Figure 1a or Figure 1b. For example, as depicted in Figure 2, a mobile variation in accordance with the server-side processing architecture illustrated in Figure 1a may be implemented by replacing voice input device 102, communications box 104, and client display device 112, with an integrated, mobile, information appliance 202 such
20 as a cellular telephone or wireless personal digital assistant (wireless PDA). Mobile information appliance 202 essentially performs the functions of the replaced components. Thus, mobile information appliance 202 receives spoken natural language input requests from the user in the form of voice data, and transmits that data (preferably via wireless data receiving station 204) across communications
25 network 206 for server-side interpretation of the request, in similar fashion as described above in connection with Figure 1. Navigation of data source 210 and retrieval of desired information likewise proceeds in an analogous manner as described above. Display information transmitted electronically back to the user across network 206 is displayed for the user on the display of information appliance
30 202, and audio information is output through the appliance's speakers.

Practitioners will further appreciate, in light of the above teachings, that if mobile information appliance 202 is equipped with sufficient computational processing power, then a mobile variation of the client-side architecture exemplified in Figure 2 may similarly be implemented. In that case, the modules corresponding to request processing logic 300 would be embodied locally in the computational resources of mobile information appliance 202, and the logical flow of data would otherwise follow in a manner analogous to that previously described in connection with Figure 1b.

As illustrated in Figure 2, multiple users, each having their own client input device, may issue requests, simultaneously or otherwise, for navigation of data source 210. This is equally true (though not explicitly drawn) for the embodiments depicted in Figures 1a and 1b. Data source 210 (or 100), being a network accessible information resource, has typically already been constructed to support access requests from simultaneous multiple network users, as known by practitioners of ordinary skill in the art. In the case of server-side speech processing, as exemplified in Figures 1a and 2, the interpretation logic and error correction logic modules are also preferably designed and implemented to support queuing and multi-tasking of requests from multiple simultaneous network users, as will be appreciated by those of skill in the art.

It will be apparent to those skilled in the art that additional implementations, permutations and combinations of the embodiments set forth in Figures 1a, 1b, and 2 may be created without straying from the scope and spirit of the present invention. For example, practitioners will understand, in light of the above teachings and design considerations, that it is possible to divide and allocate the functional components of request processing logic 300 between client and server. For example, speech recognition -- in entirety, or perhaps just early stages such as feature extraction -- might be performed locally on the client end, perhaps to reduce bandwidth requirements, while natural language parsing and other necessary processing might be performed upstream on the server end, so that more extensive computational power need not be distributed locally to each client. In that case, corresponding portions of request processing logic 300, such as speech recognition engine 310 or portions

thereof, would reside locally at the client as in Figure 1b, while other component modules would be hosted at the server end as in Figures 1a and 2.

Further, practitioners may choose to implement the each of the various embodiments described above on any number of different hardware and software computing platforms and environments and various combinations thereof, including, by way of just a few examples: a general-purpose hardware microprocessor such as the Intel Pentium series; operating system software such as Microsoft Windows/CE, Palm OS, or Apple Mac OS (particularly for client devices and client-side processing), or Unix, Linux, or Windows/NT (the latter three particularly for network data servers and server-side processing), and/or proprietary information access platforms such as Microsoft's WebTV or the Diva Systems video-on-demand system.

2. Processing Methodology

The present invention provides a spoken natural language interface for interrogation of remote electronic databases and retrieval of desired information. A preferred embodiment of the present invention utilizes the basic methodology outlined in the flow diagram of Figure 4 in order to provide this interface. This methodology will now be discussed.

a. Interpreting Spoken Natural Language Requests

At step 402, the user's spoken request for information is initially received in the form of raw (acoustic) voice data by a suitable input device, as previously discussed in connection with Figures 1-2. At step 404 the voice data received from the user is interpreted in order to understand the user's request for information. Preferably this step includes performing speech recognition in order to extract words from the voice data, and further includes natural language parsing of those words in order to generate a structured linguistic representation of the user's request.

Speech recognition in step 404 is performed using speech recognition engine 310. A variety of commercial quality, speech recognition engines are readily available on the market, as practitioners will know. For example, Nuance Communications offers a suite of speech recognition engines, including Nuance 6, its current flagship product, and Nuance Express, a lower cost package for entry-level

applications. As one other example, IBM offers the ViaVoice speech recognition engine, including a low-cost shrink-wrapped version available through popular consumer distribution channels. Basically, a speech recognition engine processes acoustic voice data and attempts to generate a text stream of recognized words.

5 Typically, the speech recognition engine is provided with a vocabulary lexicon of likely words or phrases that the recognition engine can match against its analysis of acoustical signals, for purposes of a given application. Preferably, the lexicon is dynamically adjusted to reflect the current user context, as established by the preceding user inputs. For example, if a user is engaged in a dialogue with the system
10 about movie selection, the recognition engine's vocabulary may preferably be adjusted to favor relevant words and phrases, such as a stored list of proper names for popular movie actors and directors, etc. Whereas if the current dialogue involves selection and viewing of a sports event, the engine's vocabulary might preferably be adjusted to favor a stored list of proper names for professional sports teams, etc. In addition, a
15 speech recognition engine is provided with language models that help the engine predict the most likely interpretation of a given segment of acoustical voice data, in the current context of phonemes or words in which the segment appears. In addition, speech recognition engines often echo to the user, in more or less real-time, a transcription of the engine's best guess at what the user has said, giving the user an
20 opportunity to confirm or reject.

 In a further aspect of step 404, natural language interpreter (or parser) 320 linguistically parses and interprets the textual output of the speech recognition engine. In a preferred embodiment of the present invention, the natural-language interpreter attempts to determine both the meaning of spoken words (semantic processing) as
25 well as the grammar of the statement (syntactic processing), such as the Gemini Natural Language Understanding System developed by SRI International. The Gemini system is described in detail in publications entitled "Gemini: A Natural Language System for Spoken-Language Understanding" and "Interleaving Syntax and Semantics in an Efficient Bottom-Up Parser," both of which are currently available
30 online at <http://www.ai.sri.com/natural-language/projects/arpa-sls/nat-lang.html>. (Copies of those publications are also included in an information disclosure statement submitted herewith, and are incorporated herein by this reference). Briefly, Gemini

applies a set of syntactic and semantic grammar rules to a word string using a bottom-up parser to generate a logical form, which is a structured representation of the context-independent meaning of the string. Gemini can be used with a variety of grammars, including general English grammar as well as application-specific grammars. The Gemini parser is based on "unification grammar," meaning that
5 grammatical categories incorporate features that can be assigned values; so that when grammatical category expressions are matched in the course of parsing or semantic interpretation, the information contained in the features is combined, and if the feature values are incompatible the match fails.

10 It is possible for some applications to achieve a significant reduction in speech recognition error by using the natural-language processing system to re-score recognition hypotheses. For example, the grammars defined for a language parser like Gemini may be compiled into context-free grammar that, in turn, can be used directly as language models for speech recognition engines like the Nuance
15 recognizer. Further details on this methodology are provided in the publication "Combining Linguistic and Statistical Knowledge Sources in Natural-Language Processing for ATIS" which is currently available online through <http://www.ai.sri.com/natural-language/projects/arpa-sls/spnl-int.html>. A copy of this publication is included in an information disclosure submitted herewith, and is
20 incorporated herein by this reference.

In an embodiment of the present invention that may be preferable for some applications, the natural language interpreter "learns" from the past usage patterns of a particular user or of groups of users. In such an embodiment, the successfully interpreted requests of users are stored, and can then be used to enhance accuracy by
25 comparing a current request to the stored requests, thereby allowing selection of a most probable result.

b. Constructing Navigation Queries

In step 405 request processing logic 300 identifies and selects an appropriate online data source where the desired information (in this case, current weather reports
30 for a given city) can be found. Such selection may involve look-up in a locally stored table, or possibly dynamic searching through an online search engine, or other online

search techniques. For some applications, an embodiment of the present invention may be implemented in which only access to a particular data source (such as a particular vendor's proprietary content database) is supported; in that case, step 405 may be trivial or may be eliminated entirely.

5 Step 406 attempts to construct a navigation query, reflecting the interpretation of step 404. This operation is preferably performed by query construction logic 330.

A "navigation query" means an electronic query, form, series of menu selections, or the like; being structured appropriately so as to navigate a particular data source of interest in search of desired information. In other words, a navigation
10 query is constructed such that it includes whatever content and structure is required in order to access desired information electronically from a particular database or data source of interest.

For example, for many existing electronic databases, a navigation query can be embodied using a formal database query language such as Standard Query
15 Language (SQL). For many databases, a navigation query can be constructed through a more user-friendly interactive front-end, such as a series of menus and/or interactive forms to be selected or filled in. SQL is a standard interactive and programming language for getting information from and updating a database. SQL is both an ANSI and an ISO standard. As is well known to practitioners, a Relational Database
20 Management System (RDBMS), such as Microsoft's Access, Oracle's Oracle7, and Computer Associates' CA-OpenIngres, allow programmers to create, update, and administer a relational database. Practitioners of ordinary skill in the art will be thoroughly familiar with the notion of database navigation through structured query, and will be readily able to appreciate and utilize the existing data structures and
25 navigational mechanisms for a given database, or to create such structures and mechanisms where desired.

In accordance with the present invention, the query constructed in step 406 must reflect the user's request as interpreted by the speech recognition engine and the NL parser in step 404. In embodiments of the present invention wherein data source
30 110 (or 210 in the corresponding embodiment of Figure 2) is a structured relational database or the like, step 406 of the present invention may entail constructing an

appropriate Structured Query Language (SQL) query or the like, or automatically filling out a front-end query form, series of menus or the like, as described above.

In many existing Internet (and Intranet) applications, an online electronic data source is accessible to users only through the medium of interaction with a so-called
5 Common Gateway Interface (CGI) script. Typically the user who visits a web site of this nature must fill in the fields of an online interactive form. The online form is in turn linked to a CGI script, which transparently handles actual navigation of the associated data source and produces output for viewing by the user's web browser. In other words, direct user access to the data source is not supported, only mediated
10 access through the form and CGI script is offered.

For applications of this nature, an advantageous embodiment of the present invention "scrapes" the scripted online site where information desired by a user may be found in order to facilitate construction of an effective navigation query. For example, suppose that a user's spoken natural language request is: "What's the weather
15 in Miami?" After this request is received at step 402 and interpreted at step 404, assume that step 405 determines that the desired weather information is available online through the medium of a CGI-scripted interactive form. Step 406 is then preferably carried out using the expanded process diagrammed in Figure 5. In particular, at sub-step 520, query construction logic 330 electronically "scrapes" the
20 online interactive form, meaning that query construction logic 330 automatically extracts the format and structure of input fields accepted by the online form. At sub-step 522, a navigation query is then constructed by instantiating (filling in) the extracted input format -- essentially an electronic template -- in a manner reflecting the user's request for information as interpreted in step 404. The flow of control then
25 returns to step 407 of Figure 4. Ultimately, when the query thus constructed by scraping is used to navigate the online data source in step 408, the query effectively initiates the same scripted response as if a human user had visited the online site and had typed appropriate entries into the input fields of the online form.

In the embodiment just described, scraping step 520 is preferably carried out
30 with the assistance of an online extraction utility such as WebL. WebL is a scripting language for automating tasks on the World Wide Web. It is an imperative,

interpreted language that has built-in support for common web protocols like HTTP and FTP, and popular data types like HTML and XML. WebL's implementation language is Java, and the complete source code is available from Compaq. In addition, step 520 is preferably performed dynamically when necessary -- in other
5 words, on-the-fly in response to a particular user query -- but in some applications it may be possible to scrape relatively stable (unchanging) web sites of likely interest in advance and to cache the resulting template information.

It will be apparent, in light of the above teachings, that preferred embodiments of the present invention can provide a spoken natural language interface atop an
10 existing, non-voice data navigation system, whereby users can interact by means of intuitive natural language input not strictly conforming to the linear browsing architecture or other artifacts of an existing menu/text/click navigation system. For example, users of an appropriate embodiment of the present invention for a video-on-demand application can directly speak the natural request: "Show me the movie
15 'Unforgiven'" -- instead of walking step-by-step through a typically linear sequence of genre/title/actor/director menus, scrolling and selecting from potentially long lists on each menu, or instead of being forced to use an alphanumeric keyboard that cannot be as comfortable to hold or use as a lightweight remote control. Similarly, users of an appropriate embodiment of the present invention for a web-surfing application in
20 accordance with the process shown in Figure 5 can directly speak the natural request: "Show me a one-month price chart for Microsoft stock" -- instead of potentially having to navigate to an appropriate web site, search for the right ticker symbol, enter/select the symbol, and specify display of the desired one-month price chart, each of those steps potentially involving manual navigation and data entry to one or more
25 different interaction screens. (Note that these examples are offered to illustrate some of the potential benefits offered by appropriate embodiments of the present invention, and not to limit the scope of the invention in any respect.)

c. Error Correction

Several problems can arise when attempting to perform searches based on
30 spoken natural language input. As indicated at decision step 407 in the process of Figure 4, certain deficiencies may be identified during the process of query

construction, before search of the data source is even attempted. For example, the user's request may fail to specify enough information in order to construct a navigation query that is specific enough to obtain a satisfactory search result. For example, a user might orally request "what's the weather?" whereas the national
5 online data source identified in step 405 and scraped in step 520 might require specifying a particular city.

Additionally, certain deficiencies and problems may arise following the navigational search of the data source at step 408, as indicated at decision step 409 in Figure 4. For example, with reference to a video-on-demand application, a user may
10 wish to see the movie "Unforgiven", but perhaps the user can't recall name of the film, but knows it was directed by and starred actor Clint Eastwood. A typical video-on-demand database might indeed be expected to allow queries specifying the name of a leading actor and/or director, but in the case of this query -- as in many cases -- that will not be enough to narrow the search to a single film, and additional user input in
15 some form is required.

In the event that one or more deficiencies in the user's spoken request, as processed, result in the problems described, either at step 407 or 409, some form of error handling is in order. A straightforward, crude technique might be for the system to respond simply *"input not understood / insufficient; please try again."* However,
20 that approach will likely result in frustrated users, and is not optimal or even acceptable for most applications. Instead, a preferred technique in accordance with the present invention handles such errors and deficiencies in user input at step 412, whether detected at step 407 or step 409, by soliciting additional input from the user in a manner taking advantage of the partial construction already performed and via
25 user interface modalities in addition to spoken natural language ("multi-modality"). This supplemental interaction is preferably conducted through client display device 112 (202, in the embodiment of Figure 2), and may include textual, graphical, audio and/or video media. Further details and examples are provided below. Query refinement logic 340 preferably carries out step 412. The additional input received
30 from the user is fed into and augments interpreting step 404, and query construction step 406 is likewise repeated with the benefit of the augmented interpretation. These operations, and subsequent navigation step 408, are preferably repeated until no

remaining problems or deficiencies are identified at decision points 407 or 409. Further details and examples for this query refinement process are provided immediately below.

Consider again the example in which the user of a video-on-demand application wishes to see "Unforgiven" but can only recall that it was directed by and
5 starred Clint Eastwood. First, it bears noting that using a prior art navigational interface, such as a conventional menu interface, will likely be relatively tedious in this case. The user can proceed through a sequence of menus, such as Genre (select "western"), Title (skip), Actor ("Clint Eastwood"), and Director ("Clint Eastwood").
10 In each case --especially for the last two items -- the user would typically scroll and select from fairly long lists in order to enter his or her desired name, or perhaps use a relatively couch-unfriendly keypad to manually type the actor's name twice.

Using a preferred embodiment of the present invention, the user instead speaks aloud, holding remote control microphone 102, "I want to see that movie starring and
15 directed by Clint Eastwood. Can't remember the title." At step 402 the voice data is received. At step 404 the voice data is interpreted. At step 405 an appropriate online data source is selected (or perhaps the system is directly connected to a proprietary video-on-demand provider). At step 406 a query is automatically constructed by the query construction logic 330 specifying "Clint Eastwood" in both the actor and
20 director fields. Step 407 detects no obvious problems, and so the query is electronically submitted and the data source is navigated at step 408, yielding a list of several records satisfying the query (e.g., "Unforgiven", "True Crime", "Absolute Power", etc.). Step 409 detects that additional user input is needed to further refine the query in order to select a particular film for viewing.

At that point, in step 412 query refinement logic 340 might preferably
25 generate a display for client display device 112 showing the (relatively short) list of film titles that satisfy the user's stated constraints. The user can then preferably use a relatively convenient input modality, such as buttons on the remote control, to select the desired title from the menu. In a further preferred embodiment, the first title on
30 the list is highlighted by default, so that the user can simply press an "OK" button to choose that selection. In a further preferred feature, the user can mix input modalities

by speaking a response like "I want number one on the list." Alternatively, the user can preferably say, "Let's see Unforgiven," having now been reminded of the title by the menu display.

Utilizing the user's supplemental input, request processing logic 300 iterates
5 again through steps 404 and 406, this time constructing a fully-specified query that specifically requests the Eastwood film "Unforgiven." Step 408 navigates the data source using that query and retrieves the desired film, which is then electronically transmitted in step 410 from network server 108 to client display device 112 via communications network 106.

10 Now consider again the example in which the user of a web surfing application wants to know his or her local weather, and simply asks, "what's the weather?" At step 402 the voice data is received. At step 404 the voice data is interpreted. At step 405 an online web site providing current weather information for major cities around the world is selected. At step 406 and sub-step 520, the online
15 site is scraped using a WebL-style tool to extract an input template for interacting with the site. At sub-step 522, query construction logic 330 attempts to construct a navigation query by instantiating the input template, but determines (quite rightly) that a required field -- name of city -- cannot be determined from the user's spoken request as interpreted in step 404. Step 407 detects this deficiency, and in step 412
20 query refinement logic 340 preferably generates output for client display device 112 soliciting the necessary supplemental input. In a preferred embodiment, the output might display the name of the city where the user is located highlighted by default. The user can then simply press an "OK" button -- or perhaps mix modalities by saying "yes, exactly" -- to choose that selection. A preferred embodiment would further
25 display an alphabetical scrollable menu listing other major cities, and/or invite the user to speak or select the name of the desired city.

Here again, utilizing the user's supplemental input, request processing logic 300 iterates through steps 404 and 406. This time, in performing sub-step 520, a cached version of the input template already scraped in the previous iteration might
30 preferably be retrieved. In sub-step 522, query construction logic 330 succeeds this time in instantiating the input template and constructing an effective query, since the

desired city has now been clarified. Step 408 navigates the data source using that query and retrieves the desired weather information, which is then electronically transmitted in step 410 from network server 108 to client display device 112 via communications network 106.

5 It is worth noting that in some instances, there may be details that are not explicitly provided by the user, but that query construction logic 330 or query refinement logic 340 may preferably deduce on their own through reasonable assumptions, rather than requiring the use to provide explicit clarification. For example, in the example previously described regarding a request for a weather
10 report, in some applications it might be preferable for the system to simply assume that the user means a weather report for his or her home area and to retrieve that information, if the cost of doing so is not significantly greater than the cost of asking the user to clarify the query. Making such an assumption might be even more strongly justified in a preferred embodiment, as described earlier, where user histories
15 are tracked, and where such history indicates that a particular user or group of users typically expect local information when asking for a weather forecast. At any rate, in the event such an assumption is made, if the user actually intended to request the weather for a different city, the user would then need to ask his or her question again. It will be apparent to practitioners, in light of the above teachings, that the choice of
20 whether to program query construction logic 330 and query refinement logic 340 to make make particular assumptions will typically involve trade-offs involving user convenience that can be assessed in the context of specific applications.

3. Open Agent Architecture (OAA®)

Open Agent Architecture™ (OAA®) is a software platform, developed by the assignee of the present invention, that enables effective, dynamic collaboration among communities of distributed electronic agents. OAA is described in greater detail in co-pending U.S. Patent Application No. 09/225,198, which has been incorporated
5 herein by reference. Very briefly, the functionality of each client agent is made available to the agent community through registration of the client agent's capabilities with a facilitator. A software "wrapper" essentially surrounds the underlying application program performing the services offered by each client. The common
10 infrastructure for constructing agents is preferably supplied by an *agent library*. The agent library is preferably accessible in the runtime environment of several different programming languages. The agent library preferably minimizes the effort required to construct a new system and maximizes the ease with which legacy systems can be "wrapped" and made compatible with the agent-based architecture of the present
15 invention. When invoked, a client agent makes a connection to a facilitator, which is known as its *parent facilitator*. Upon connection, an agent registers with its parent facilitator a specification of the capabilities and services it can provide, using a high-level, declarative Interagent Communication Language ("*ICL*") to express those capabilities. Tasks are presented to the facilitator in the form of ICL goal expressions.
20 When a facilitator determines that the registered capabilities of one of its client agents will help satisfy a current goal or sub-goal thereof, the facilitator delegates that sub-goal to the client agent in the form of an ICL request. The client agent processes the request and returns answers or information to the facilitator. In processing a request, the client agent can use *ICL* to request services of other agents, or utilize other
25 infrastructure services for collaborative work. The facilitator coordinates and integrates the results received from different client agents on various sub-goals, in order to satisfy the overall goal.

OAA provides a useful software platform for building systems that integrate spoken natural language as well as other user input modalities. For example, see the
30 above-referenced co-pending patent application, especially Figure 13 and the corresponding discussion of a "multi-modal maps" application, and Figure 12 and the

corresponding discussion of a "unified messaging" application. Another example is the InfoWiz interactive information kiosk developed by the assignee and described in the document entitled "InfoWiz: An Animated Voice Interactive Information System" available online at <http://www.ai.sri.com/~oaa/applications.html>. A copy of the
5 InfoWhiz document is provided in an Information Disclosure Statement submitted herewith and incorporated herein by this reference. A further example is the "CommandTalk" application developed by the assignee for the U.S. military, as described online at <http://www.ai.sri.com/~lesaf/commandtalk.html> and in the following publications, copies of which are provided in an Information Disclosure
10 Statement submitted herewith and incorporated herein by this reference:

- "CommandTalk: A Spoken-Language Interface for Battlefield Simulations", 1997, by Robert Moore, John Dowding, Harry Bratt, J. Mark Gawron, Yonael Gorfu and Adam Cheyer, in "Proceedings of the Fifth Conference on Applied Natural Language Processing", Washington,
15 DC, pp. 1-7, Association for Computational Linguistics
- "The CommandTalk Spoken Dialogue System", 1999, by Amanda Stent, John Dowding, Jean Mark Gawron, Elizabeth Owen Bratt and Robert Moore, in "Proceedings of the Thirty-Seventh Annual Meeting of the
20 ACL", pp. 183-190, University of Maryland, College Park, MD, Association for Computational Linguistics
- "Interpreting Language in Context in CommandTalk", 1999, by John Dowding and Elizabeth Owen Bratt and Sharon Goldwater, in
25 "Communicative Agents: The Use of Natural Language in Embodied Systems", pp. 63-67, Association for Computing Machinery (ACM) Special Interest Group on Artificial Intelligence (SIGART), Seattle, WA

For some applications and systems, OAA can provide an advantageous platform for constructing embodiments of the present invention. For example, a
30 representative application is now briefly presented, with reference to Figure 6. If the statement "show me movies starring John Wayne" is spoken into the voice input device, the voice data for this request will be sent by UI agent 650 to facilitator 600, which in turn will ask natural language (NL) agent 620 and speech recognition agent 610 to interpret the query and return the interpretation in *ICL* format. The resulting
35 *ICL* goal expression is then routed by the facilitator to appropriate agents -- in this case, video-on-demand database agent 640 -- to execute the request. Video database agent 640 preferably includes or is coupled to an appropriate embodiment of query construction logic 330 and query refinement logic 340, and may also issue *ICL*

requests to facilitator 600 for additional assistance -- e.g., display of menus and capture of additional user input in the event that query refinement is needed -- and facilitator 600 will delegate such requests to appropriate client agents in the community. When the desired video content is ultimately retrieved by video database agent 640, UI agent 650 is invoked by facilitator 600 to display the movie.

Other spoken user requests, such as a request for the current weather in New York City or for a stock quote, would eventually lead facilitator to invoke web database agent 630 to access the desired information from an appropriate Internet site. Here again, web database agent 630 preferably includes or is coupled to an appropriate embodiment of query construction logic 330 and query refinement logic 340, including a scraping utility such as WebL. Other spoken requests, such as a request to view recent emails or access voice mail, would lead the facilitator to invoke the appropriate email agent 660 and/or telephone agent 680. A request to record a televised program of interest might lead facilitator 600 to invoke web database agent 630 to return televised program schedule information, and then invoke VCR controller agent 680 to program the associated VCR unit to record the desired television program at the scheduled time.

Control and connectivity embracing additional electronic home appliances (e.g., microwave oven, home surveillance system, etc.) can be integrated in comparable fashion. Indeed, an advantage of OAA-based embodiments of the present invention, that will be apparent to practitioners in light of the above teachings and in light of the teachings disclosed in the cited co-pending patent applications, is the relative ease and flexibility with which additional service agents can be plugged into the existing platform, immediately enabling the facilitator to respond dynamically to spoken natural language requests for the corresponding services.

4. Further Embodiments and Equivalents

While the present invention has been described in terms of several preferred embodiments, there are many alterations, permutations, and equivalents that may fall within the scope of this invention. It should also be noted that there are many
5 alternative ways of implementing the methods and apparatuses of the present invention. It is therefore intended that the following appended claims be interpreted as including all such alterations, permutations, and equivalents as fall within the true spirit and scope of the present invention.

Claims

What is claimed is:

1. A method for speech-based navigation of an electronic data source, the electronic data source having a scripted online interface and being located at one or more network servers located remotely from a user, comprising the steps of:
 - (a) receiving a spoken request for desired information from the user;
 - (b) rendering an interpretation of the spoken request;
 - (c) dynamically scraping the online scripted interface to the data source, to
5 extract an input template;
 - (d) constructing a navigation query based upon the interpretation of step (b) and the template of step (c);
 - (e) using the navigation query to select a portion of the electronic data source; and
 - 10 (f) transmitting the selected portion of the electronic data source from the network server to a client device of the user.
2. The method of claim 1, wherein the online scripted interface is a web site.
3. The method of claim 1, wherein the input template is extracted from an online form of the scripted interface.
- 15 4. The method of claim 1, wherein the step of rendering an interpretation further includes deriving linguistic information by using a speech recognition engine and a linguistic parser.
5. The method of claim 1, wherein at least one of the steps of rendering an interpretation and constructing a navigation query are performed, at least in part, on a
20 computing device located locally with the user.

6. The method of claim 1, wherein at least one of the steps of rendering an interpretation and constructing a navigation query are performed, at least in part, on a network computing device located remotely from the user.
7. The method of claim 1, further comprising the step of soliciting additional
5 input in response to one or more deficiencies encountered during the step of constructing the navigation query.
8. The method of claim 7, wherein the deficiencies include unresolved words of the spoken request.
9. The method of claim 7, wherein the deficiencies include one or more required
10 elements of the navigational query not determinable from the interpretation of the spoken request.
10. The method of claim 7, wherein the step of soliciting additional input is performed in response to one or more deficiencies encountered after a first navigation of the data source using the navigation query constructed in step (d).
11. The method of claim 10, wherein the deficiencies include existence of more
15 than one data record within the data source responsive to the navigation query.
12. The method of claim 10, wherein the deficiencies include failure to identify a single data record within the data source responsive to the navigation query.
13. The method of claim 7, further comprising the steps of:
- 20 (a) receiving the additional input from the user
- (b) refining the navigational query based on the additional input;
- (c) determining whether the navigational query is deemed adequate;
- 25 (d) soliciting additional input if the navigational query is not deemed adequate and repeating steps (a)-(c) until the navigational query is deemed adequate.

14. The method of claim 7, wherein a determination that deficiencies exist in the navigational query is at least partially based on a user-input statement that additional information is required.
15. The method of claim 7, wherein the additional input is solicited by presenting
5 a menu to the user on the client device of the user.
16. The method of claim 7, wherein the additional input is solicited by presenting a textual request for the additional input.
17. The method of claim 7, wherein the additional input is solicited by outputting an audible request for the additional input.
- 10 18. The method of claim 7, wherein the additional input is solicited by presenting a list of portions of the electronic data source that match the navigational query.
19. The method of claim 7, wherein the additional input received from the user is at least partially speech based.
20. The method of claim 7, wherein the additional input received from the user
15 includes no spoken input.
21. The method of claim 1, wherein the method is performed with respect to a plurality of simultaneous users and corresponding client devices.
22. The method of claim 1, further including the step of selecting the data source from among a plurality of candidate electronic data sources, in response to the
20 interpretation of the spoken request.
23. The method of claim 1, wherein at least a portion of a communications link between the client device and the data source is the Internet.
24. A system for speech-based navigation of an electronic data source, the electronic data source having a scripted online interface and being located at one or
25 more network servers located remotely from a user, the system comprising:
- (a) a portable microphone operable to receive a spoken request for desired information from the user;

- (b) language processing logic, operable to render an interpretation of the spoken request;
- (c) template extraction logic, operable to dynamically scrape the online scripted interface to the data source, to extract an input template;
- 5 (d) query construction logic, operable to construct a navigation query based upon the interpretation rendered by the language processing logic and the template extracted by the template extraction logic;
- (e) navigation logic, operable to select a portion of the electronic data source using the navigation query; and
- 10 (f) electronic communications infrastructure for transmitting the selected portion of the electronic data source from the network server to a client device of the user.

25. The system of claim 24, wherein the online scripted interface is a web site.

26. The system of claim 24, wherein the input template is extracted from an online
15 *form of the scripted interface.*

27. The system of claim 24, wherein the language processing logic includes speech recognition logic and linguistic parsing logic for deriving linguistic information.

28. The system of claim 24, wherein at least a portion of the language processing
20 logic is hosted on a computing device located locally with the user.

29. A computer program embodied on a computer readable medium for utilizing spoken natural language for navigating an electronic data source, the electronic data source having a scripted online interface and being located at one or more network servers located remotely from a user, comprising:

- 25 (a) a code segment that receives a spoken natural language ("NL") request for desired information from the user;

- (b) a code segment that renders an interpretation of the spoken natural language request;
- (c) a code segment that dynamically scrapes the online scripted interface to the data source, to extract an input template;
- 5 (d) a code segment that constructing a navigation query based upon the interpretation of step (b) and the template of step (c);
- (e) a code segment that uses the navigation query to select a portion of the electronic data source; and a code segment that transmits the selected portion of the electronic data source from the network server to a client
10 device of the user.

30. The system of claim 24, further comprising user interaction logic for soliciting additional input in response to one or more deficiencies encountered during the constructing the navigation query.

15 31. The system of claim 30, wherein the deficiencies include unresolved words of the spoken request.

32. The system of claim 30, wherein the deficiencies include one or more required elements of the navigational query not determinable from the interpretation of the spoken request.

20 33. The system of claim 30, wherein the user interaction logic solicits additional input in response to one or more deficiencies encountered after a first navigation of the data source using the navigation query constructed by the query construction logic.

34. The system of claim 33, wherein the deficiencies include existence of more than one data record within the data source responsive to the navigation query.

25 35. The system of claim 33, wherein the deficiencies include failure to identify a single data record within the data source responsive to the navigation query.

36. The system of claim 24 wherein the navigation logic selects the data source from among a plurality of candidate electronic data sources, in response to the interpretation of the spoken request.

37. The system of claim 24, wherein at least a portion of the electronic
5 communications infrastructure is the Internet.

38. A computer program embodied on a computer readable medium for speech-based navigation of an electronic data source, the electronic data source having a scripted online interface and being located at one or more network servers located remotely from a user, comprising:

- 10 (a) a code segment that receives a spoken request for desired information from the user;
- (b) a code segment that renders an interpretation of the spoken request;
- (c) a code segment that dynamically scrapes the online scripted interface to the data source, to extract an input template;
- 15 (d) a code segment that constructing a navigation query based upon the interpretation of step (b) and the template of step (c);
- (e) a code segment that uses the navigation query to select a portion of the electronic data source; and
- (f) a code segment that transmits the selected portion of the electronic data
20 source from the network server to a client device of the user.

39. The computer program of claim 38, wherein the online scripted interface is a web site.

40. The computer program of claim 38, wherein the input template is extracted from an online form of the scripted interface.

25 41. The computer program of claim 38, further comprising a code segment that derives linguistic information by using a speech recognition engine and a linguistic parser.

42. The computer program of claim 38, wherein the rendering of the interpretation and construction of the navigation query are performed, at least in part, on a computing device located locally with the user.

43. The computer program of claim 38, wherein the rendering of the interpretation
5 and construction of the navigation query are performed, at least in part, on a network computing device located remotely from the user.

44. The computer program of claim 38, further comprising a code segment that solicits additional input in response to one or more deficiencies encountered during construction of the navigation query.

10 45. The computer program of claim 45, wherein the deficiencies include unresolved words of the spoken request.

46. The computer program of claim 45, wherein the deficiencies include one or more required elements of the navigational query not determinable from the interpretation of the spoken request.

15 47. The computer program of claim 45, wherein the code segment that solicits additional input solicits the additional input in response to one or more deficiencies encountered after a first navigation of the data source using the navigation query.

48. The computer program of claim 47, wherein the deficiencies include existence of more than one data record within the data source responsive to the navigation
20 query.

40. The computer program of claim 47, wherein the deficiencies include failure to identify a single data record within the data source responsive to the navigation query.

41. The computer program of claim 44, further comprising the steps of:

- (a) a code segment that receives the additional input from the user
- 25 (b) a code segment that refines the navigational query based on the additional input;

- (c) a code segment that determines whether the navigational query is deemed adequate;
- (d) a code segment that solicits additional input if the navigational query is not deemed adequate and repeating steps (a)-(c) until
- 5 the navigational query is deemed adequate.

42. The computer program of claim 44, wherein a determination that deficiencies exist in the navigational query is at least partially based on a user-input statement that additional information is required.

43. The computer program of claim 44, wherein the additional input is solicited

10 by presenting a menu to the user on the client device of the user.

44. The computer program of claim 44, wherein the additional input is solicited by presenting a textual request for the additional input.

45. The computer program of claim 44, wherein the additional input is solicited by outputting an audible request for the additional input.

15 46. The computer program of claim 44, wherein the additional input is solicited by presenting a list of portions of the electronic data source that match the navigational query.

47. The computer program of claim 44, wherein the additional input received from the user is at least partially speech based.

20 48. The computer program of claim 44, wherein the additional input received from the user includes no spoken input.

49. The computer program of claim 38, wherein the code segments of the computer program operate with respect to a plurality of simultaneous users and corresponding client devices.

25 50. The computer program of claim 38, further including a code segment that selects the data source from among a plurality of candidate electronic data sources, in response to the interpretation of the spoken request.

51. The computer program of claim 38, wherein at least a portion of a communications link between the client device and the data source is the Internet.

52. A method for utilizing spoken natural language for navigating an electronic data source, the electronic data source having a scripted online interface and being
5 located at one or more network servers located remotely from a user, comprising the steps of:

- (a) receiving a spoken natural language ("NL") request for desired information from the user;
- (b) rendering an interpretation of the spoken natural language request;
- 10 (c) dynamically scraping the online scripted interface to the data source, to extract an input template;
- (d) constructing a navigation query based upon the interpretation of step (b) and the template of step (c);
- (e) using the navigation query to select a portion of the electronic data
15 source; and
- (f) transmitting the selected portion of the electronic data source from the network server to a client device of the user.

53. The method of claim 52, wherein the online scripted interface is a web site.

54. The method of claim 52, wherein the input template is extracted from an
20 online form of the scripted interface.

55. The method of claim 52, wherein the step of rendering an interpretation further includes deriving linguistic information by using a speech recognition engine and an NL parser.

56. The method of claim 52, wherein at least one of the steps of rendering an
25 interpretation and constructing a navigation query are performed, at least in part, on a computing device located locally with the user.

57. The method of claim 52, wherein at least one of the steps of rendering an interpretation and constructing a navigation query are performed, at least in part, on a network computing device located remotely from the user.

58. The method of claim 52, further comprising the step of soliciting additional
5 input in response to one or more deficiencies encountered during the step of constructing the navigation query.

59. The method of claim 58, wherein the deficiencies include unresolved words of the spoken NL request.

60. The method of claim 58, wherein the deficiencies include one or more
10 required elements of the navigational query not determinable from the interpretation of the spoken NL request.

61. The method of claim 58, wherein the step of soliciting additional input is performed in response to one or more deficiencies encountered after a first navigation of the data source using the navigation query constructed in step (d).

62. The method of claim 61, wherein the deficiencies include existence of more
15 than one data record within the data source responsive to the navigation query.

63. The method of claim 61, wherein the deficiencies include failure to identify a single data record within the data source responsive to the navigation query.

64. The method of claim 52, wherein the method is performed with respect to a
20 plurality of simultaneous users and corresponding client devices.

65. The method of claim 52, further including the step of selecting the data source from among a plurality of candidate electronic data sources, in response to the interpretation of the spoken NL request.

66. The method of claim 52, wherein at least a portion of a communications link
25 between the client device and the data source is the Internet.

67. A system for utilizing spoken natural language for navigating an electronic data source, the electronic data source having a scripted online interface and being

located at one or more network servers located remotely from a user, the system comprising:

- (a) a portable microphone operable to receive a spoken natural language ("NL") request for desired information from the user;
- 5 (b) spoken language processing logic, operable to render an interpretation of the spoken natural language request;
- (c) template extraction logic, operable to dynamically scrape the online scripted interface to the data source, to extract an input template;
- 10 (d) query construction logic, operable to construct a navigation query based upon the interpretation rendered by the spoken language processing logic and the template extracted by the template extraction logic;
- (e) navigation logic, operable to select a portion of the electronic data source using the navigation query; and
- 15 (f) electronic communications infrastructure for transmitting the selected portion of the electronic data source from the network server to a client device of the user.

68. The system of claim 67, wherein the online scripted interface is a web site.

69. The system of claim 67, wherein the input template is extracted from an
20 online form of the scripted interface.

70. The system of claim 67, wherein the spoken language processing logic includes speech recognition logic and an NL parsing logic for deriving linguistic information.

71. The system of claim 67, wherein at least a portion of the spoken language
25 processing logic is hosted on a computing device located locally with the user.

72. The system of claim 67, further comprising user interaction logic for soliciting additional input in response to one or more deficiencies encountered during the constructing the navigation query.

73. The system of claim 72, wherein the deficiencies include unresolved words of
5 the spoken NL request.

74. The system of claim 72, wherein the deficiencies include one or more required elements of the navigational query not determinable from the interpretation of the spoken NL request.

75. The system of claim 72, wherein the user interaction logic solicits additional
10 input in response to one or more deficiencies encountered after a first navigation of the data source using the navigation query constructed by the query construction logic.

76. The system of claim 75, wherein the deficiencies include existence of more than one data record within the data source responsive to the navigation query.

77. The system of claim 75, wherein the deficiencies include failure to identify a
15 single data record within the data source responsive to the navigation query.

78. The system of claim 67, wherein the navigation logic selects the data source from among a plurality of candidate electronic data sources, in response to the interpretation of the spoken NL request.

79. The system of claim 67, wherein at least a portion of the electronic
20 communications infrastructure is the Internet.

80. A computer program embodied on a computer readable medium for utilizing spoken natural language for navigating an electronic data source, the electronic data source having a scripted online interface and being located at one or more network
25 servers located remotely from a user, comprising:

- (f) a code segment that receives a spoken natural language ("NL") request for desired information from the user;

- (g) a code segment that renders an interpretation of the spoken natural language request;
- (h) a code segment that dynamically scrapes the online scripted interface to the data source, to extract an input template;
- 5 (i) a code segment that constructing a navigation query based upon the interpretation of step (b) and the template of step (c);
- (j) a code segment that uses the navigation query to select a portion of the electronic data source; and
- 10 (k) a code segment that transmits the selected portion of the electronic data source from the network server to a client device of the user.

81. The computer program of claim 80, wherein the online scripted interface is a web site.

82. The computer program of claim 80, wherein the input template is extracted from an online form of the scripted interface.

- 15 83. The computer program of claim 80, further comprising a code segment that derives linguistic information by using a speech recognition engine and an NL parser.

84. The computer program of claim 80, wherein the rendering of the interpretation and construction of the navigation query are performed, at least in part, on a computing device located locally with the user.

- 20 85. The computer program of claim 80, wherein the rendering of the interpretation and construction of the navigation query are performed, at least in part, on a network computing device located remotely from the user.

86. The computer program of claim 80, further comprising a code segment that solicits additional input in response to one or more deficiencies encountered during
25 construction of the navigation query.

87. The computer program of claim 86, wherein the deficiencies include unresolved words of the spoken NL request.

88. The computer program of claim 86, wherein the deficiencies include one or more required elements of the navigational query not determinable from the interpretation of the spoken NL request.

89. The computer program of claim 86, wherein the code segment that solicits additional input solicits the additional input in response to one or more deficiencies encountered after a first navigation of the data source using the navigation query.

90. The computer program of claim 89, wherein the deficiencies include existence of more than one data record within the data source responsive to the navigation query.

91. The computer program of claim 89, wherein the deficiencies include failure to identify a single data record within the data source responsive to the navigation query.

92. The computer program of claim 80, wherein the code segments of the computer program operate with respect to a plurality of simultaneous users and corresponding client devices.

93. The computer program of claim 80, further including a code segment that selects the data source from among a plurality of candidate electronic data sources, in response to the interpretation of the spoken NL request.

94. The computer program of claim 80, wherein at least a portion of a communications link between the client device and the data source is the Internet.
